CONVERSION TABLE

For the convenience of readers who may want to use the International Systems of Units (SI), the data may be converted by using the following factors:

<u>Multiply inch-pound units</u>	<u>by</u>	<u>To obtain SI units</u>
inches (in)	25.4 2.54	millimeters (mm) centimeters (cm)
inches per day (in/d)	25.4 2.54	millimeters per day (mm/d) centimeters per day (cm/d)
feet (ft)	0.3048	meters (m)
miles (mi)	1.609	kilometers (km)
miles per hour (mi/hr)	1.609	kilometers per hour (km/hr)
miles per day (mi/d)	1.609	kilometers per day (km/d)
acres	4047.	square meters (m^2)
acre-feet (acre-ft)	1233.	cubic meters (m^3)
degrees Fahrenheit ($^{\circ}\text{F}$)	0.56($^{\circ}\text{F}-32$)	degree Celsius ($^{\circ}\text{C}$)

Specific Combinations

$$1 \text{ Acre-ft} = 226.2 \text{ gal/min, during one day}$$

$$1 \text{ ft}^3/\text{s} = 448.8 \text{ gal/min}$$

$$1 \text{ ft}^3/\text{s} = 0.65 \text{ Mgal/d}$$

CLIMATOLOGICAL DATA FOR THE RICE-GROWING AREAS ALONG THE NORTH COAST OF PUERTO RICO

By

Angel J. Román-Más and Bruce Green

ABSTRACT

Rainfall, temperature, wind velocity and pan evaporation data were collected from May 1983 to September 1985, in the rice-growing areas of Vega Baja, Manatí, and Arecibo in northern Puerto Rico. Daily values and statistics including mean, standard deviation, extremes, and totals for each month of record were compiled. Descriptions of equipment installation and operation, data processing, and significance of climatological data for rice cultivation are presented.

INTRODUCTION

In 1983, the Caribbean District office of the U.S. Geological Survey, Water Resources Division (USGS) in cooperation with the Puerto Rico Department of Agriculture (PRDOA), began an investigation to determine the quantity of water required for irrigation in the rice-growing areas of Arecibo, Manatí, and Vega Baja (fig. 1). As part of this investigation, a weather station was located at each area (fig. 2, 3, and 4). Rainfall, temperature, wind velocity, and pan evaporation data were collected daily from May 1983 to September 1985. Climatological data was used

to define the prevailing weather conditions during the crop cycles measured.

This report summarizes the rainfall, temperature, wind velocity, and pan evaporation data collected at each weather station (fig. 2, 3, 4, and 5). Means and extreme values, standard deviations, and totals for the month (tables 1, 2, and 3) are included.

Acknowledgments

The authors gratefully acknowledge the assistance provided by hydrologic technicians José Merced and Ana Sánchez in the instrument installation as well as in the collection and processing of the data.

INSTRUMENTATION

Each station was equipped with a rain gage, a maximum-minimum thermometer, an evaporation pan, and an anemometer. Equipment installation and operation as well as data collection by the USGS technical staff was in accordance with standard National Oceanographic and Atmospheric Administration (NOAA) methods and procedures criteria.

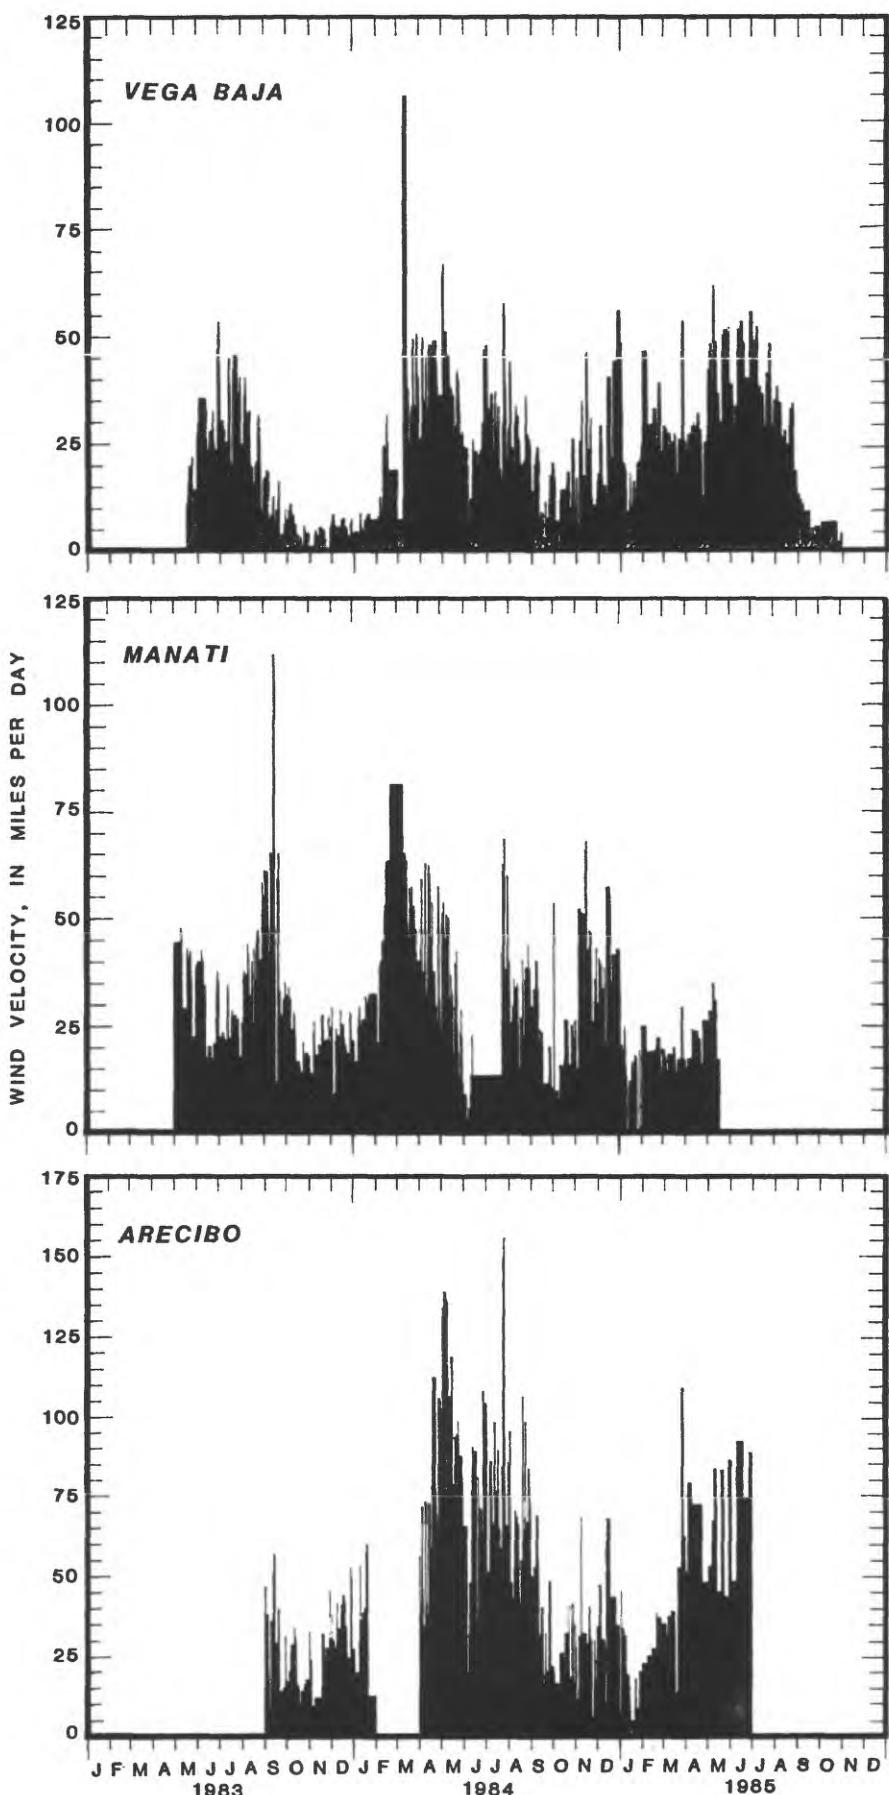

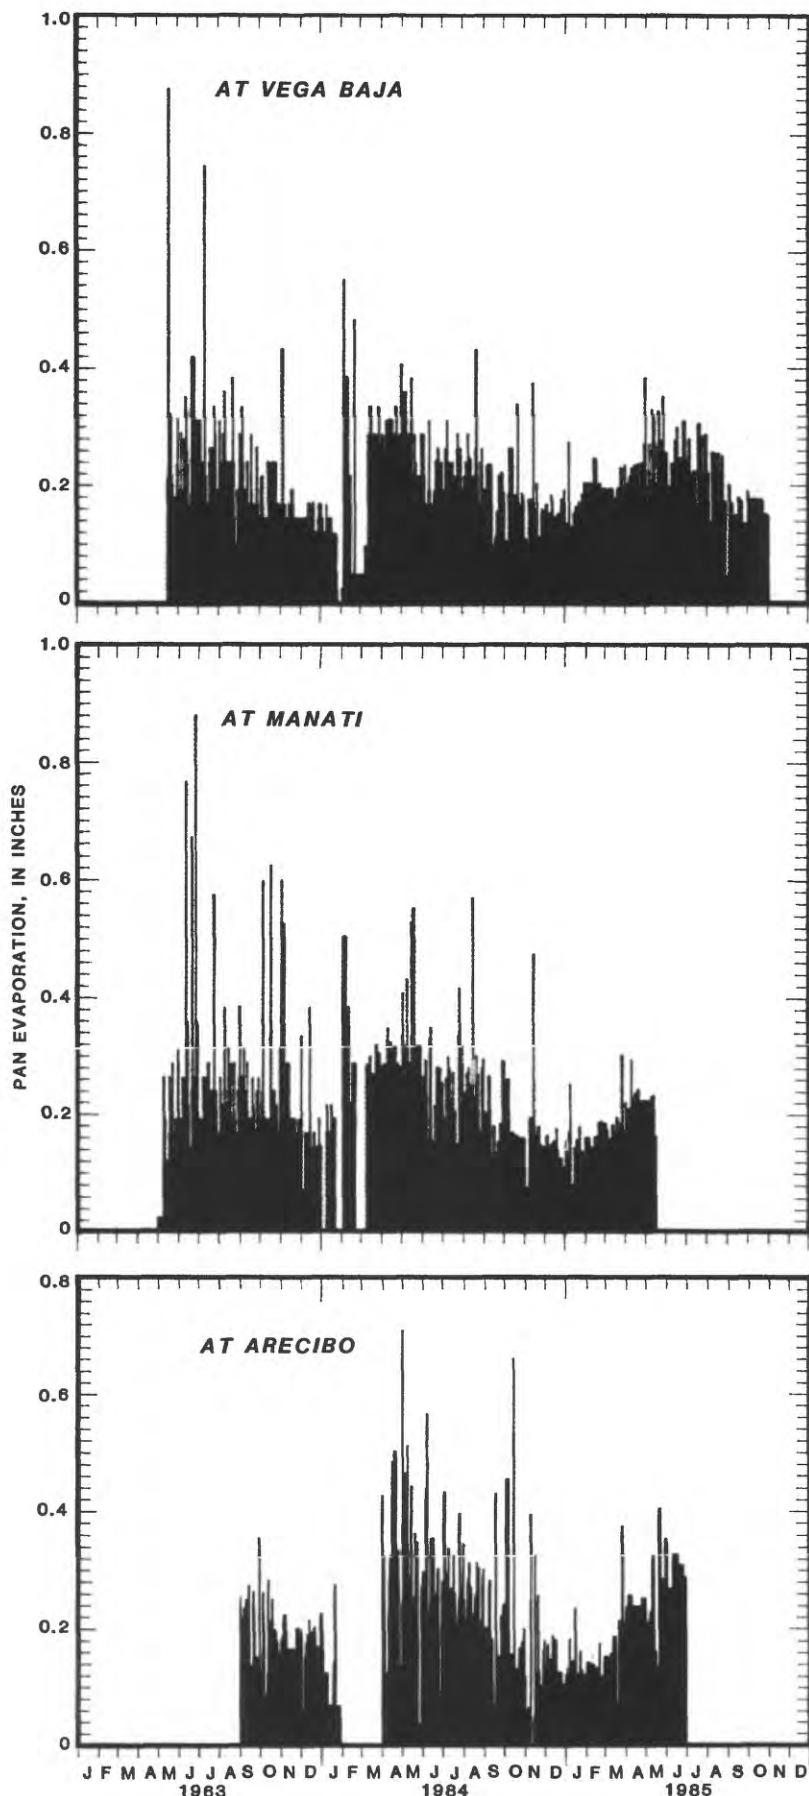

Figure 4.--Daily wind velocity at the Vega Baja, Manati, and Arecibo weather stations.

**Figure 5.--Daily pan evaporation at the Vega Baja, Manati,
and Arecibo weather stations.**

INSTRUMENTATION--Continued

Rainfall was measured with an 8-inch non-recording gage made of either plastic or metal. The gage consists of an overflow can, measuring tub, rainfall funnel, measuring stick, and support (fig. 6). The top of the funnel is exactly 8-inches inside diameter. The funnel empties the rainfall into a cylindrical measuring tub. To facilitate measurement of rainfall to hundredths of an inch, the measuring tube has a cross-section area that is one-tenth the top area of the funnel. The scale of the

measuring stick used with the tube is expanded 10 times, and since the scale is graduated to hundredths of an inch, the correct rainfall depth of water in the tube is read directly to hundredths from the stick. The measuring tube is 20 inches in height and holds exactly 2.00 inches of rainfall. Any additional rainfall will overflow into the outer can. Water from the can is poured into an empty tube for direct measurement with the stick. The measuring tube of the plastic model has been graduated to hundredths of an inch to read directly without using the stick.

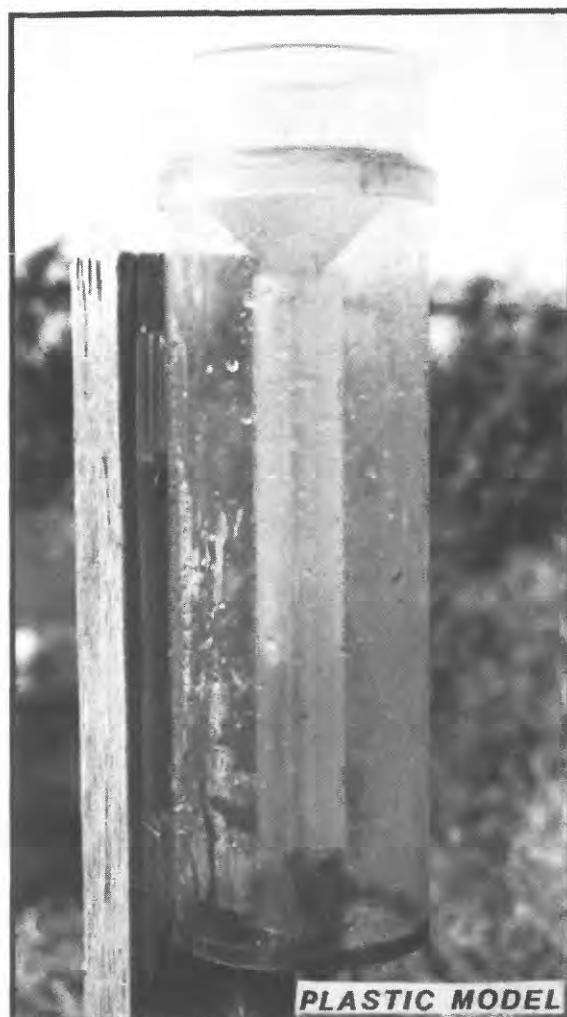

Figure 6.--Two 8-inch nonrecording rainfall gages (copper and plastic models).

INSTRUMENTATION--Continued

The Weather Measure Model E8-11 (Use of trade names by the USGS does not imply endorsement of the products depicted), Submersible Minimum-Maximum Thermometer was used to measure minimum and maximum temperatures. It consists of a plastic backing with a glass U tube containing two metal indices - one to indicate minimum temperature and one to indicate maximum temperature. In addition, the glass U tube contains a liquid filling and a mercury column. Two temperature scales are permanently marked on the U tube, one for low temperatures and the other for high temperatures (fig. 7). In operation, as the temperature changes, the liquid filling located above the mercury columns in both legs of the U tube, expands or contracts depending upon whether or not the temperature is rising or falling. If the temperature is rising, the mercury column in the right-hand leg of the U tube rises. If the temperature is falling, the mercury column in the left-hand leg of the U tube rises. As the mercury column rises, in either the left-hand or right-hand leg of the U tube, it pushes the metal index up higher in the tube. When the mercury column falls, in either leg of the U tube, the metal index remains in place as an indication of the highest or lowest temperature which was reached during the observation period. The bottom edge of the metal index is always read in order to obtain the maximum or minimum temperature.

At the completion of an observation, the metal indices are reset with a small magnet until their lower edges are in contact with the mercury column. The thermometers were mounted on a

vertical post near the center of a U.S. National Weather Service (USNWS) medium-sized type shelter. The shelter has louvered sides with a double top designed to protect the thermometers from precipitation, condensation, and radiation. The louvered construction permits air to circulate freely through the shelter.

A five-digit odometer type, 3-cup anemometer was used for measuring wind movement. It is mounted on the wooden evaporation pan support in order to measure the wind movement over the pan. The five digits appearing in the window of the meter (fig. 8) indicate the total wind movement to tenths of a mile for any total from zero to 10,000 miles. The right-hand digit indicates tenths of a mile. Ten thousand miles is indicated as five zeros (00000) on the meter and coincides with zero miles for the succeeding 10,000-mile cycle of operation. If 24-hour wind movement computation is desired, the previous reading has to be subtracted from the current day reading.

The U.S. National Weather Service "Class A" land Pan was used to measure evaporation. This instrument is used at all official USNWS and cooperative stations in the United States. It is made of unpainted galvanized iron, 4 ft in diameter, and 10 inches deep (fig. 9). The bottom, supported on a wooden frame, is raised 6-inches above the ground surface. The water surface, maintained between 2- and 3-inches below the rim of the pan, is measured daily with a hook-gage in a stilling well. The daily evaporation is computed as the difference between observed water levels, correlated for any precipitation measured in an adjacent or standard rain gage.

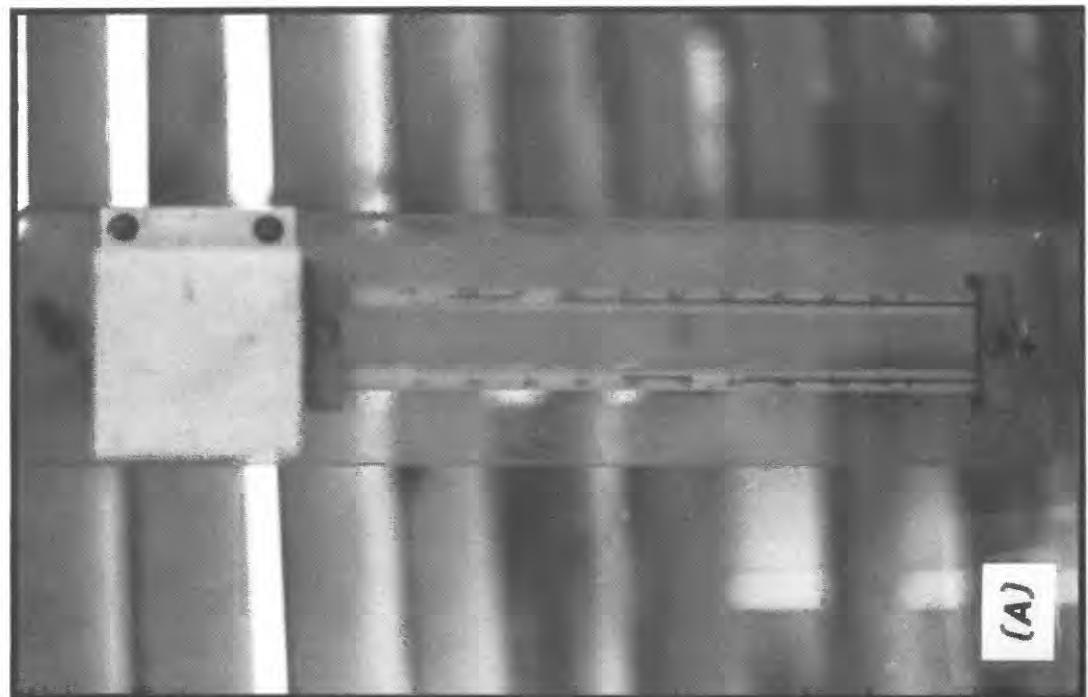

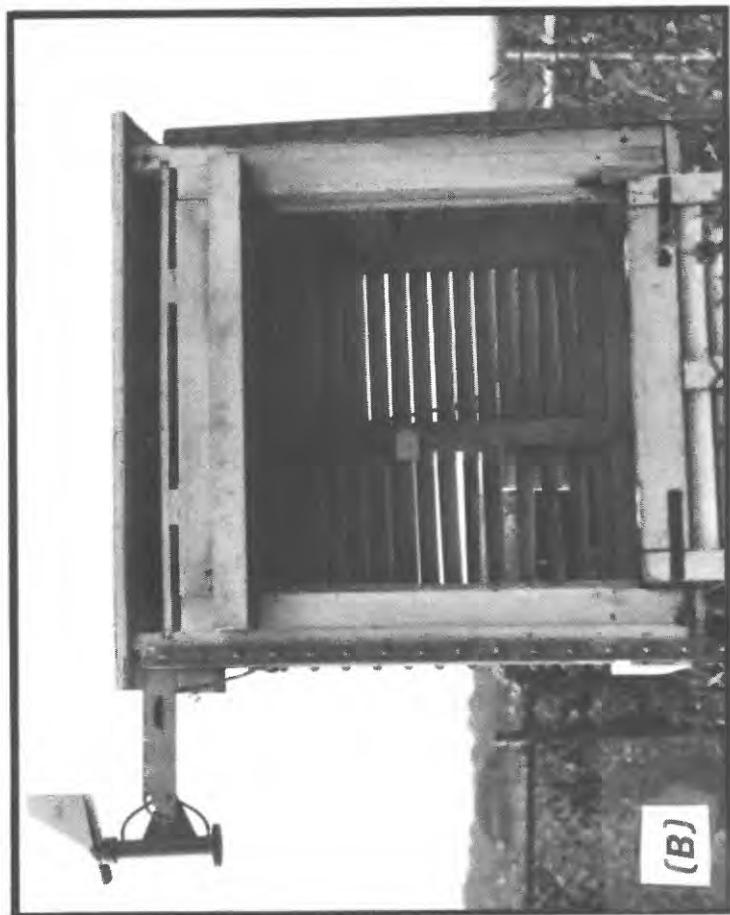

Figure 7--A submersible minimum-maximum thermometer, Model E8-11 (letter A) and a Weather Service medium-sized shelter (letter B).

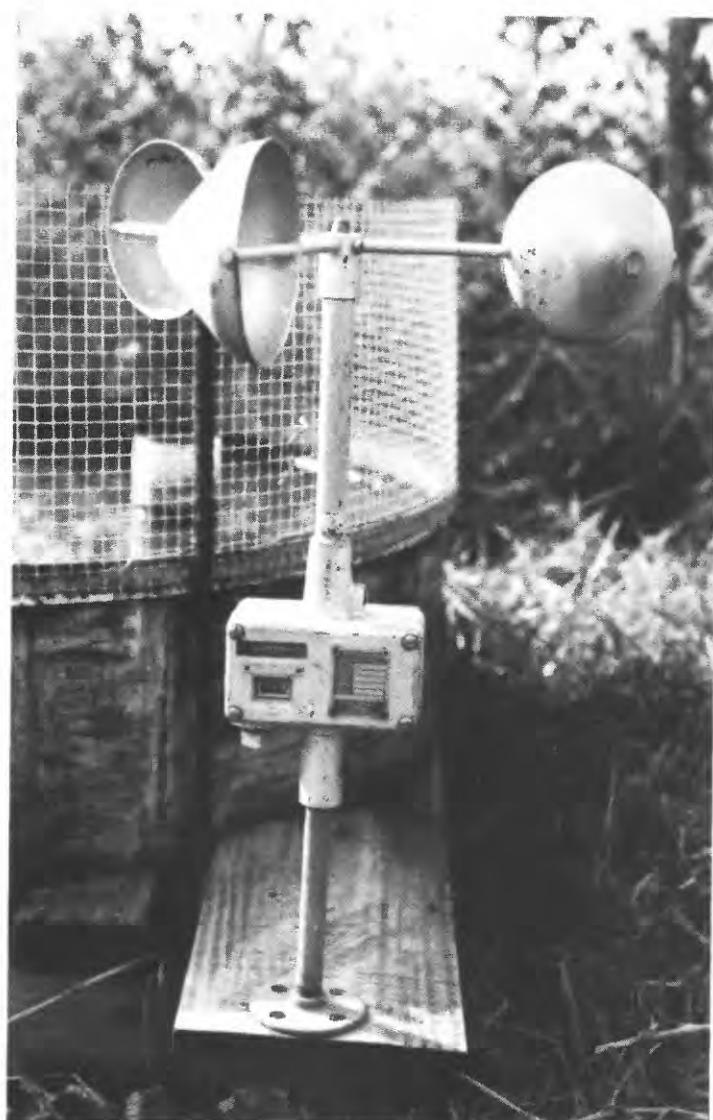

Figure 8.--A 5-digit odometer type, 3-cup anemometer.

INSTRUMENTATION--Continued

A micrometer hook-gage (fig. 10) was used to measure water level in the evaporation pan. The gage consists of a hook in the end of a stem that is graduated to tenths of inches over a range of several inches. The stem is constructed with double threads throughout its range of adjustment. The threads have a pitch of one-tenth of an inch. A three-legged spider and adjusting-nut assembly supports the hook and provides for adjustment of the height of the hook when the gage is installed on the stilling well. The adjusting nut is threaded to screw on the stem of the hook. After assembly, the gage is placed on the stilling well with the three legs of the spider resting on the top rim of the well and the hook centered in the well. The adjusting nut is free to turn within the spider so that it may be used conveniently to adjust the height of the hook. The relative height of the hook in the well is indicated by the scales of the gage.

SIGNIFICANCE OF CLIMATOLOGICAL DATA FOR RICE CULTIVATION

Climate is a critical factor in defining the suitability of specific areas for rice cultivation. As an example, rice grows well when partially submerged in water. In comparison to other grains, it requires large amounts of water for maximum yield (weeds control). In addition to accessibility to large supplies of water

(rainfall, river, lakes, aquifers) areas suitable for rice cultivation should have warm temperatures, low winds, and low evaporation rates (Vicente-Chandler, 1977).

The total amount of water required by a crop for its normal growth is defined as the water lost by evapotranspiration and infiltration, plus the amount of water required by the irrigation technique utilized (in the case of rice continuous flooding). Experiments conducted by Silva and Vicente-Chandler (1982, p. 185) and Román-Más (1985, p.16) indicated that about 2.90 acre-ft/acre of the 4 acre-ft/acre (73 percent) of water required for rice irrigation is evapotranspired. The use of pan evaporation values to estimate actual evapotranspiration is a widely accepted technique. A series of correlations utilizing temperature, wind velocity, and pan evaporation data might provide a theoretical model by which evapotranspiration can be estimated for other areas.

Irrigation required is the quantity of water other than from precipitation that has to be supplied for crop production. For a rice crop it can be determined by subtracting the precipitation during a period of 120 consecutive days (which is approximately the duration of a crop cycle for rice) from the water required. Data collected indicate that rainfall provides from 0.28 acre-ft/acre (7 percent) to 2.43 (61 percent) of the total water required. This assumes an efficient use of the rainfall, which may or may not be possible.
